AUTHENTICATION REFERRAL SEARCH FOR LDAP

BACKGROUND OF THE INVENTION

1. Technical Field:

The present invention relates to computer network environments. More specifically, the present invention relates to directory services within a computer network.

2. Description of Related Art:

Lightweight Directory Access Protocol (LDAP) is a protocol that facilitates access to specialized directory servers within a computer network. LDAP provides a referral model which allows client computers to ask an LDAP server a question and be told to contact another The contacted server can return any of the server. requested information which it possesses. In addition, the contacted server returns a list of other servers which might contain the requested information. The LDAP clients, in this case, are responsible for contacting all of the other servers to complete the search request.

One of the major problems associated with the referral mechanism is that the user needs to bind to other servers, with different Distinguished Names (DN's) existing on these servers. Without this binding, the referred search becomes an unauthenticated request. Unauthenticated requests make managing multiple directories impossible.

30

Therefore, it would be desirable to have a method

Express Mail No. EL356874379US

Docket No.AUS920000806US1

which allows a user to manage information stored on all servers without having his or her account physically reside on every server.

authenticated and is denied.

SUMMARY OF THE INVENTION

The present invention provides a method, program and system for authenticating LDAP referral searches. The invention comprises receiving a bind request from a LDAP referred search request and then searching the local directory for an entry corresponding to the distinguished name (DN) of the bind request. If an entry for the bind DN is located within the local directory, the bind 10 request is authenticated. If an entry for the bind DN is not found in the local directory, a defined reference server is checked for the prefix of the bind DN. If the prefix for the bind DN is located in the reference server, the reference server is contacted for 15 authentication, which is performed using a root DN. an entry for the bind DN is not found in either the local

directory or reference server, the bind request cannot be

BRIEF DESCRIPTION OF THE DRAWINGS

The novel features believed characteristic of the

invention are set forth in the appended claims. The
invention itself, however, as well as a preferred mode of
use, further objectives and advantages thereof, will best
be understood by reference to the following detailed
description of an illustrative embodiment when read in

conjunction with the accompanying drawings, wherein:

Figure 1 depicts a pictorial representation of a network of data processing systems in which the present invention may be implemented;

Figure 2 depicts a block diagram of a data processing system that may be implemented as a server in accordance with a preferred embodiment of the present invention;

Figure 3 depicts a block diagram illustrating a data processing system in which the present invention may be implemented; and

Figure 4 depicts a flowchart illustrating an authenticated referral search in accordance with the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

With reference now to the figures, Figure 1 depicts a

5 pictorial representation of a network of data processing
systems in which the present invention may be implemented.
Network data processing system 100 is a network of
computers in which the present invention may be
implemented. Network data processing system 100 contains
10 a network 102, which is the medium used to provide
communications links between various devices and computers
connected together within network data processing system

100. Network 102 may include connections, such as wire,

wireless communication links, or fiber optic cables.

In the depicted example, a server 104 is connected to network 102 along with storage unit 106. In addition, clients 108, 110, and 112 also are connected to network 102. These clients 108, 110, and 112 may be, for example, personal computers or network computers. In the depicted example, server 104 provides data, such as boot files, operating system images, and applications to clients 108-112. Clients 108, 110, and 112 are clients to server

In the depicted example, network data processing system 100 is the Internet with network 102 representing a worldwide collection of networks and gateways that use the TCP/IP suite of protocols to communicate with one another. At the heart of the Internet is a backbone of high-speed data communication lines between major nodes or host

104. Network data processing system 100 may include

additional servers, clients, and other devices not shown.

computers, consisting of thousands of commercial, government, educational and other computer systems that route data and messages. Of course, network data processing system 100 also may be implemented as a number of different types of networks, such as for example, an intranet, a local area network (LAN), or a wide area network (WAN). Figure 1 is intended as an example, and not as an architectural limitation for the present invention.

Referring to Figure 2, a block diagram of a data 10 processing system that may be implemented as a server, such as server 104 in Figure 1, is depicted in accordance with a preferred embodiment of the present invention. Data processing system 200 may be a symmetric multiprocessor (SMP) system including a plurality of 15 processors 202 and 204 connected to system bus 206. Alternatively, a single processor system may be employed. Also connected to system bus 206 is memory controller/cache 208, which provides an interface to local memory 209. I/O bus bridge 210 is connected to system bus 20 206 and provides an interface to I/O bus 212. Memory controller/cache 208 and I/O bus bridge 210 may be integrated as depicted.

Peripheral component interconnect (PCI) bus bridge
214 connected to I/O bus 212 provides an interface to PCI
25 local bus 216. A number of modems may be connected to PCI
bus 216. Typical PCI bus implementations will support
four PCI expansion slots or add-in connectors.
Communications links to network computers 108-112 in
Figure 1 may be provided through modem 218 and network
30 adapter 220 connected to PCI local bus 216 through add-in

25

30

boards.

Additional PCI bus bridges 222 and 224 provide interfaces for additional PCI buses 226 and 228, from which additional modems or network adapters may be supported. In this manner, data processing system 200 allows connections to multiple network computers. A memory-mapped graphics adapter 230 and hard disk 232 may also be connected to I/O bus 212 as depicted, either directly or indirectly.

Those of ordinary skill in the art will appreciate that the hardware depicted in Figure 2 may vary. For example, other peripheral devices, such as optical disk drives and the like, also may be used in addition to or in place of the hardware depicted. The depicted example is not meant to imply architectural limitations with respect to the present invention.

The data processing system depicted in Figure 2 may be, for example, an IBM RISC/System 6000 system, a product of International Business Machines Corporation in Armonk, New York, running the Advanced Interactive Executive (AIX) operating system.

With reference now to Figure 3, a block diagram illustrating a data processing system is depicted in which the present invention may be implemented. Data processing system 300 is an example of a client computer. Data processing system 300 employs a peripheral component interconnect (PCI) local bus architecture. Although the depicted example employs a PCI bus, other bus architectures such as Accelerated Graphics Port (AGP) and Industry Standard Architecture (ISA) may be used. Processor 302 and main memory 304 are connected to PCI

local bus 306 through PCI bridge 308. PCI bridge 308 also may include an integrated memory controller and cache memory for processor 302. Additional connections to PCI local bus 306 may be made through direct component

- interconnection or through add-in boards. In the depicted example, local area network (LAN) adapter 310, SCSI host bus adapter 312, and expansion bus interface 314 are connected to PCI local bus 306 by direct component connection. In contrast, audio adapter 316, graphics
- adapter 318, and audio/video adapter 319 are connected to PCI local bus 306 by add-in boards inserted into expansion slots. Expansion bus interface 314 provides a connection for a keyboard and mouse adapter 320, modem 322, and additional memory 324. Small computer system interface
- 15 (SCSI) host bus adapter 312 provides a connection for hard disk drive 326, tape drive 328, and CD-ROM drive 330.

 Typical PCI local bus implementations will support three or four PCI expansion slots or add-in connectors.

An operating system runs on processor 302 and is used to coordinate and provide control of various components within data processing system 300 in Figure 3. The operating system may be a commercially available operating system, such as Windows 2000, which is available from Microsoft Corporation. An object oriented programming system such as Java may run in conjunction with the

operating system and provide calls to the operating system from Java programs or applications executing on data processing system 300. "Java" is a trademark of Sun Microsystems, Inc. Instructions for the operating system,

30 the object-oriented operating system, and applications or

20

programs are located on storage devices, such as hard disk drive 326, and may be loaded into main memory 304 for execution by processor 302.

Those of ordinary skill in the art will appreciate

that the hardware in Figure 3 may vary depending on the implementation. Other internal hardware or peripheral devices, such as flash ROM (or equivalent nonvolatile memory) or optical disk drives and the like, may be used in addition to or in place of the hardware depicted in

Figure 3. Also, the processes of the present invention may be applied to a multiprocessor data processing system.

As another example, data processing system 300 may be a stand-alone system configured to be bootable without relying on some type of network communication interface, whether or not data processing system 300 comprises some type of network communication interface. As a further example, data processing system 300 may be a Personal Digital Assistant (PDA) device, which is configured with ROM and/or flash ROM in order to provide non-volatile memory for storing operating system files and/or user-generated data.

The depicted example in **Figure 3** and above-described examples are not meant to imply architectural

limitations. For example, data processing system 300 also may be a notebook computer or hand held computer in addition to taking the form of a PDA. Data processing system 300 also may be a kiosk or a Web appliance.

Lightweight Directory Access Protocol (LDAP) is used to access directory services in a computer network. Directory services serve as central repository for

15

20

25

30

searching, adding, deleting and modifying data. The original directory services specification was X.500, which heavily consumes network and system resources. LDAP was established primarily to enable less powerful clients to access X.500 services. LDAP provides an application program interface (API) for accessing directory services, querying, reading and writing data.

Before a client can access a directory's contents, it must authenticate (bind) to the directory. In general, bind consists of providing a user ID and password. In the case of a LDAP directory, the user ID is referred to as a distinguished name (DN). The DN used to bind to a directory is the bind DN, which usually corresponds to the name of an entry in the directory. The entry corresponding to the bind DN will represent a person or an organization. The bind DN and the

corresponding password must be known to the directory.

Referring now to Figure 4, a flowchart illustrating an authenticated referral search is depicted in accordance with the present invention. The process begins when a client computer sends a request to a LDAP server (step 401). LDAP directory service is based on a client-server model. When a LDAP client connects to a LDAP server, the server either responds with the answer or with a pointer to where the client can get more information, which is typically another LDAP server.

The present invention relates to referral searches. Therefore, the next step is for the LDAP server to send a referral back to the client (step 402). A referral is a redirection that the directory service returns when the client requests a directory entry that does not exist on

15

20

25

30

the local server. This referral will list servers within the network that contain information that the client is seeking. The directory server will determine whether to return a referral by comparing the DN of the requested directory object against the directory suffixes supported by the local server. If the DN does not match the suffixes, a referral is returned to the client.

The referral might take the form of a "smart" referral. Essentially, a smart referral maps a directory entry or directory tree to a specific LDAP uniform resource locator (URL). This allows a directory to be scaled across multiple server without physically containing those directory entries on each server. All that is required is a referral from one entry in the local directory to an entry on some other server.

When a client is returned a referral, it automatically reformats the original LDAP request to fit the boundaries set by the referral. The client then reissues the request (step 403).

In addition to the referral entries which can be configured on the LDAP server, users can define reference servers for authenticating a client, through binding. Binding establishes a software connection between one protocol and another. Essentially, the following information is put on a server: 1) root DN's, which are the subtrees that the server is handling, and 2) server location, which is the host name and port that the server is listening to. The root DN is the distinguished name for a privileged directory user. After authentication, the root DN has complete access to the directory, regardless of access controls.

15

20

25

30

Express Mail No. EL356874379US

Docket No.AUS920000806US1

Access to a directory can be controlled with Access-Control Lists (ACLs) that are composed of a series of one or more access-control information (ACI) statements that either allow or deny certain permissions (i.e. read, write, search, compare) to specified entries and their attributes. ACL can be used to set permissions for: the entire directory, a particular subtree, specific entries, and any entry that matches a given LDAP search filter. Search filters allow administrators to set types of access for widely scattered entries that contain common attribute values.

Targets specify the entry or attribute to which an ACI applies. An ACI can target only one entry, but multiple attributes. Permissions define the type of directory access set by the ACI. Examples of permissions include read, write search, add, delete, and compare. Bind rules indicate the bind DN's to which the permissions apply. A bind rule may also specify a filter. If the filter is true for the binding client, then the ACI applies to the client.

When a server receives a bind request from a referred search request (step 404), the server will first determine if an entry for the bind DN is located locally on the server itself (step 405). If the DN is on the server, then the server performs the authentication of the referred search request itself (step 406).

If the DN cannot be located on the server, the server then checks the defined reference servers (step 407). If a prefix is found, the server contacts the defined reference server for authentication (step 408). Authentication through the reference server is based on

20

25

30

the root DN stored on the server, which allows access to the rest of the directory after the authentication of the root DN itself.

If a user attempts to modify an entry and is

referred to another LDAP URL, the client will attempt to
reformat the modification request to fit the boundaries
set by the referrals. For example, if a user is issuing
the modification request for o=IBM, ou=Austin,
cn=AdminHost1 and the request is referred to Host2, the

LDAP server on Host2 will check the referred server entry
stored on the directory server and find that Host1
contains the subtree. The rebind request will be
forwarded to Host1 for processing and the user will be
authenticated with the user information stored on Host1.

If a prefix is not found on the defined reference server, and authentication cannot be performed, the bind request from the referred search is denied (step 409).

The present invention makes administering multiple directories through referrals possible. In contrast to chaining in X.500, the client is still responsible for chasing the referrals. However, with the trust relationship established through the servers, the user will be able to manage information stored on all servers without having his or her account physically residing on every server.

It is important to note that while the present invention has been described in the context of a fully functioning data processing system, those of ordinary skill in the art will appreciate that the processes of the present invention are capable of being distributed in the form of a computer readable medium of instructions

15

and a variety of forms and that the present invention applies equally regardless of the particular type of signal bearing media actually used to carry out the distribution. Examples of computer readable media include recordable-type media, such as a floppy disk, a hard disk drive, a RAM, CD-ROMs, DVD-ROMs, and transmission-type media, such as digital and analog communications links, wired or wireless communications links using transmission forms, such as, for example, radio frequency and light wave transmissions. The computer readable media may take the form of coded formats that are decoded for actual use in a particular data processing system.

The description of the present invention has been presented for purposes of illustration and description, and is not intended to be exhaustive or limited to the invention in the form disclosed. Many modifications and variations will be apparent to those of ordinary skill in the art. The embodiment was chosen and described in order to best explain the principles of the invention, the practical application, and to enable others of ordinary skill in the art to understand the invention for various embodiments with various modifications as are suited to the particular use contemplated.
